Two analysers.

Text Inspector vs LexInspect

A controlled comparison of the live websites using one original English passage. Conducted in Helium on 16 October 2026.

Main finding
LexInspect matches Text Inspector on all visible basic statistics for this passage, both Flesch measures, and MTLD at the displayed precision. Three areas differ: Gunning Fog, voc-D, and vocabulary classification.

What is already aligned

Both tools count 194 tokens, 14 sentences, 153 unique word types and 395 syllables. Flesch Reading Ease is 20.52 and Flesch-Kincaid grade is 13.84 in both. MTLD agrees after rounding: 257.03.

What needs further validation

Gunning Fog differs by 0.21, with a concrete explanation in LexInspect's handling of an inflected word. voc-D differs substantially: 200.00 versus 245.48. Academic vocabulary coverage differs by 0.962 percentage points; the detailed Text Inspector word list is unavailable to this guest session.

Decision this evidence supports

The shared counting and readability foundation is well aligned on this sample. It is premature to claim complete numerical equivalence. Keep the results transparent, and validate voc-D and vocabulary matching on a broader set of passages before making compatibility claims.

Scope: one passage, guest access, live production websites. No source code was changed. This report compares observed outputs; it does not treat either product as an unquestioned reference standard.

Test design and exact passage

The same literal text was entered into each site. It was checked in the visible input before reading the results. An initial Text Inspector run still contained its default sample; that run was discarded and is excluded from this report.

Test condition	Value
Passage	Original British English prose about school gardens
Length	194 words; 14 sentences; 1,438 characters
Browser	Helium
LexInspect	Live site; downloaded analysis JSON
Text Inspector	Homepage Quick Analysis v1.9.0 and dashboard v2.0.0
Dashboard options	British English; Writing; target A1 (default)
Access	Guest session; no manual count amendments

Full test passage

Schools increasingly use community gardens to connect classroom learning with practical experience. In these spaces, pupils observe how plants respond to changes in light, temperature and water. They record their observations, compare results and explain why some crops develop more successfully than others. This process encourages careful reasoning rather than the simple memorisation of scientific facts.

However, establishing a garden requires more than enthusiasm. Teachers must allocate time, obtain suitable equipment and ensure that every child can participate safely. Limited funding may affect the range of activities, while poor weather can interrupt planned lessons. Cooperation with local residents can provide additional expertise and help schools maintain the garden during holidays.

The educational benefits also extend beyond science. Measuring growing areas offers opportunities to practise mathematics, and writing reports develops the ability to communicate evidence clearly. Working together may strengthen social relationships, although these outcomes depend on how responsibilities are shared. A successful programme therefore needs clear objectives and regular evaluation. Schools should examine whether the activities improve understanding, include pupils with different needs and remain manageable for staff. When these conditions are met, a modest garden can become a valuable resource for sustained learning.

Input deliberately avoids digits, contractions, abbreviations and hyphenated compounds. The test therefore checks ordinary prose rather than difficult tokenisation cases.

Measured results

Values below are taken from the visible Text Inspector dashboard and the live LexInspect JSON, except the two vocabulary percentages, which were visible only in Text Inspector's homepage Quick Analysis.

Measure	Text Inspector	LexInspect
Tokens, excluding numbers	194	194
Sentences	14	14
Unique word types	153	153
Syllables	395	395
Words with >2 syllables	53	53
Polysyllabic words (%)	27.32	27.32
Words per sentence	13.86	13.857
Syllables per word	2.04	2.036
Syllables per sentence	28.21	28.214
Syllables per 100 words	203.61	203.608
Type-token ratio	0.79	0.7887
Flesch Reading Ease	20.52	20.52
Flesch-Kincaid grade	13.84	13.84
Gunning Fog	16.47	16.26
MTLD	257.03	257.0263
voc-D	200.00	245.48
Academic vocabulary (%)	12.44	13.402
B1 vocabulary (%)	23.68	17.526

Precision: additional LexInspect decimals do not represent a disagreement when rounding produces the same displayed Text Inspector value. This applies to all averages, type-token ratio and MTLD.

Comparability: B1 percentages use different vocabulary resources. They are recorded as observations, not as equivalent measurements that should necessarily match.

Explaining the numerical differences

1. Gunning Fog: a traceable counting rule

Both sites report 53 words with more than two syllables. LexInspect uses only 52 of them as Fog-complex words. A read-only local check identifies the exclusion as **“Measuring”**: it has three syllables, while its lemma “measure” has two.

LexInspect's implementation excludes words that reach three syllables only through an -es, -ed or -ing ending, along with proper nouns and hyphenated compounds. This rule makes its Fog-complex count different from its general polysyllabic count.

Reconciliation
Using 52 complex words: 0.4 x (194/14 + 100 x 52/194) = **16.26**.
Using all 53 polysyllabic words gives **16.47**, precisely Text Inspector's result.

The arithmetic strongly supports a counting-rule explanation for this passage. Text Inspector's internal code was not inspected; its treatment of every possible suffix or exception has not been established.

2. voc-D: fitting and sampling remain unresolved

Text Inspector shows 200 in both its homepage and dashboard. LexInspect shows 245.48. Their shared MTLD result means this is a difference in one diversity estimator, rather than a general disagreement about the text's observed word variety.

LexInspect uses seeded random sampling: seed 42, three trials, 100 samples for each sample size from 35 to 50 words. The result is reproducible for the same input. Text Inspector describes random subsampling and curve fitting, but its exact fitting settings were not verified.

Its dashboard says voc-D scores are typically between 0 and 200. That description does **not** prove a hard cap. A fitting bound or cap is a hypothesis, not a confirmed explanation. A larger test set should check whether the difference recurs, especially for highly diverse passages.

3. Academic words: word-level evidence is missing

LexInspect finds 26 AWL tokens among 194 words, or 13.402%, spanning 26 families. Text Inspector Quick Analysis reports 12.44%. Its detailed AWL view is locked, so the specific matching words and denominator behind that value cannot be verified. Neither output is established as wrong by this comparison.

CEFR and product experience

CEFR percentages are based on different resources

LexInspect uses CEFR-J plus Octanove. In this passage it assigns 34 tokens to B1 (17.526%), reaches 95% lexical coverage at B2, and leaves eight tokens off-list. The off-list words are reasoning, memorisation, allocate, funding, planned, expertise, manageable and sustained.

Text Inspector uses the English Vocabulary Profile. Its Quick Analysis reports 23.68% of words at B1. Without its detailed EVP breakdown, the exact word classifications and denominator cannot be reconciled. Different resources, part-of-speech handling and inflection rules can affect coverage.

Avoid a misleading CEFR comparison
LexInspect's B2 lexical coverage estimate is not equivalent to an overall writing proficiency score. Text Inspector's guest dashboard displayed a locked C2 label even before the test passage was entered; this report does not treat that label as a verified result.

What LexInspect makes accessible

In this session, LexInspect exposes detailed AWL and CEFR breakdowns, metadiscourse analysis, additional readability and diversity measures, and a JSON download. That makes it easier to inspect the basis of a result and preserve reproducible evidence.

What Text Inspector does well

Its dashboard explains measures beside the results and offers explicit British English and analysis-mode settings. Statistics can be amended, which can help users correct a segmentation or syllable error before recalculating dependent scores. These are useful product patterns for LexInspect to consider.

What guest access prevented

EVP, detailed AWL, metadiscourse and Scorecard were locked in the Text Inspector dashboard. We did not subscribe, create an account, or bypass those restrictions. Its homepage nevertheless exposed summary academic-word and B1 percentages, which are labelled separately in this report.

Experience findings are qualitative

The session demonstrates accessibility and explanatory differences, not a measured usability or performance study. No comparable load-time, mobile interaction, accessibility audit or task-completion timing was performed.

Recommended follow-up and evidence

Priority	Action	Reason
1	Validate voc-D on a varied passage set	Separate sampling variation, fitting bounds and implementation choices.
2	Reconcile AWL matches word by word when detailed access is available	Resolve the percentage difference using actual matches and denominators.
3	Document the Gunning Fog exclusion in the UI	Make the explainable 0.21 difference understandable to users.
4	Test segmentation edge cases	Add abbreviations, contractions, hyphens, digits and short sentences.
5	Consider contextual explanations and editable counts	Support users who need to understand or correct a result.

Limits of the conclusion

One controlled passage is insufficient to establish general accuracy or full compatibility. Matching totals can conceal different per-word decisions. Rounded equality does not prove identical implementation. Guest access limits vocabulary diagnosis, and randomised diversity estimates need repeated or controlled comparisons. The recommended follow-ups are proposed work, not completed validation.

Evidence files

passage.txt - exact original input, with a trailing file newline.
lexinspect-live.json - download from the live LexInspect UI.
comparison.md - detailed working record, including the numerical reconciliation.

These files are in reports/text-inspector-comparison/ in the LexInspect project. The analysed string trims the trailing file newline. Input SHA-256:
